I have a project that has several repositories linked to it. Repo A includes an extern to a folder in Repo B. When a commit is made to Repo A the associated issue displays the associated revision entry twice. Both are identical. When a commit is made to Repo B, it's done correctly with a single entry. The commits are not spanning the repos over the extern, they are entirely within one repo or the other.

Attached picture shows the first entry only once because it's done to Repo B. The rest are commits to Repo A.

We do have the option to fetch commits automatically turned off and instead we run a cron job using "redmine:fetch_changesets" to update it.

Database manager version: Mysql2
Ruby version: 2.1.5-p273 (2014-11-13) [x86_64-linux-gnu]
Rails version: 4.2.8
Redmine version: 3.4.3.stable
scm binary version: svn 1.8.10

That was my first thought too, but then I carefully re-read the (brief) description given by the OP. It explicitly states that they are using multiple (svn) repos per project along with svn externals pointing to parts of the other linked repos. It says nothing about the use of subprojects.

Based on that I don't see how this issue is known as #6857. I rather think that this is a more complex issue which has to do with the svn externals feature, and possibly in combination with the multiple repo feature of Redmine.

What do you think?

Yes, we have no sub-projects. It looks like comment #7 on #6857 is similar, so this problem likely has been around a while. I tried looking at the source code and didn't see

anything obvious that would explain it.

related_issues

duplicates,New,6857,git references leaking from subproject to project
